

# Signal Integrity Solutions

Find Problems Now,  
Prevent Problems Next Time

**Agilent Technologies**

## A New Perspective on the Design Process

**In all evolving technologies, you eventually reach a point where you must change your way of thinking to go past a certain level. The methods and rules of thumb you have used in the past are no longer adequate. To move forward, you must step back and look at the design process from a new perspective.**

**To move to the next level in high-speed digital design, with sub-nanosecond edge rates and slim design margins, you must add additional problem solving tools to your trusty toolbox. The ubiquitous oscilloscope, though important, requires complementary software and/or instrumentation to adequately address today's difficult signal integrity and jitter issues.**

Agilent is constantly researching new ways to assist design engineers and has developed a comprehensive set of tools that will keep signal integrity problems under control as you move into higher-speed designs. Instead of relying on guessing and the old rules of thumb, you can measure critical components and create accurate models to simulate and verify your new designs before committing them to hardware. Once the hardware is built, you can accurately measure the physical layer to validate the signal paths prior to installing components.

When the components are first installed, you can use pulse generators to test your system with live signals. High-speed scopes and active probes enable you to see what is going on. Once the system is running, you can monitor the signal integrity of

hundreds of channels simultaneously with a logic analyzer and eye diagram feature, eye scan. An oscilloscope or bit error ratio tester (BERT) help characterize jitter.

Signal integrity is no longer something to be looked at just once at the beginning of a project when laying out the device or board. Everyone must be aware of signal integrity and evaluate it throughout the project, and must have the proper tools to accomplish this sometimes daunting task. The challenging high-speed digital designs of today's data rates require careful use of a wide variety of engineering tools. It is important for designers to learn these new tools effectively to avoid multiple re-design efforts.

The breadth of tools available from Agilent Technologies enables signal integrity evaluation throughout the entire design process. You can use a vector network analyzer (VNA) or time domain reflectometer (TDR) for device and interconnect characterization. The measurement data is used to enhance your model database so that design simulation will produce accurate results. For those who do not want to invest in the equipment and expertise for characterization, Agilent can provide device characterization and modeling services.

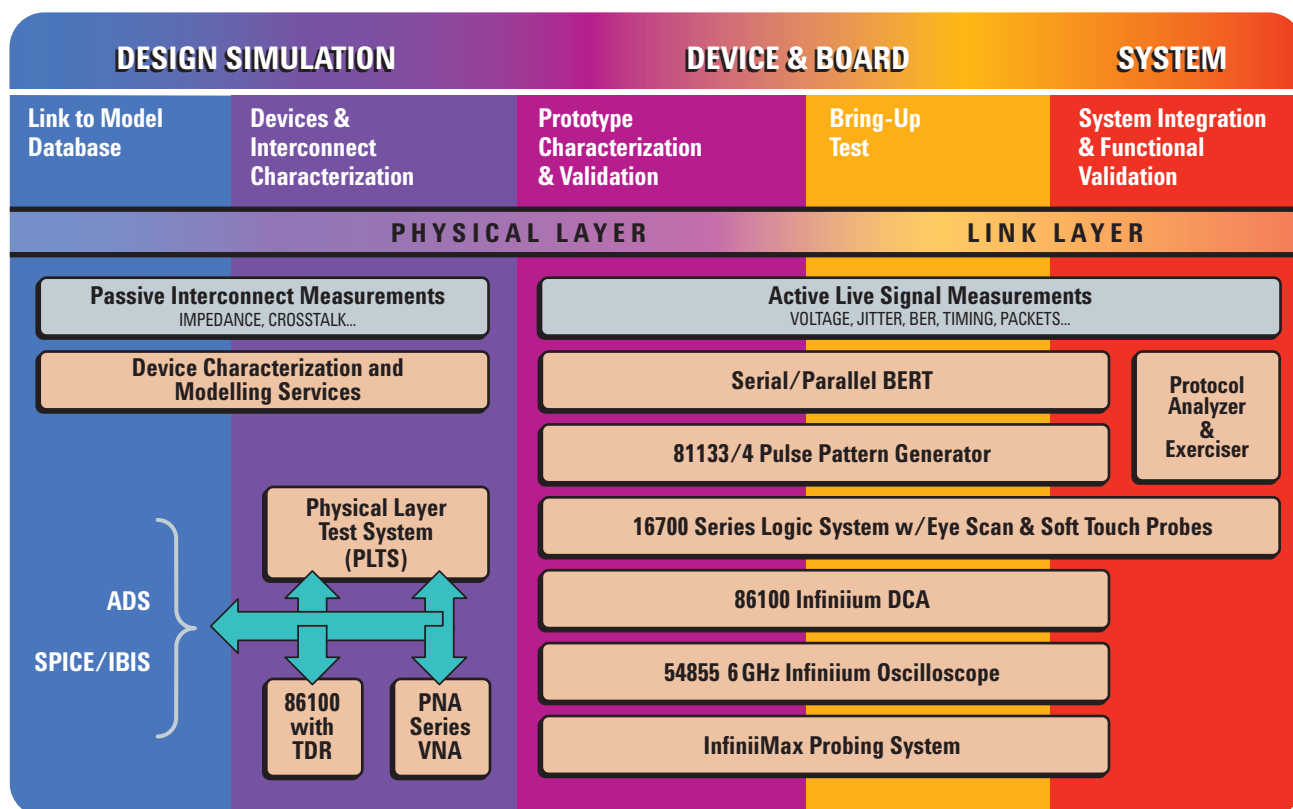

Once the device or board is created, a wide variety of tools from Agilent enable you to

characterize the physical layer of your design. After you are satisfied with the results, you can install components and bring the system up. Capable pulse pattern generators can provide live signals to stimulate portions of the system as you bring it up. For jitter characterization, use the histogram mode of the oscilloscope or the bathtub curve from a BERT.

When the system is running, you can use eye diagrams to validate signal quality. The eye diagram can be acquired with a scope when you want to see a few signals, or with a unique, signal integrity-aware logic analyzer if you want to check hundreds of signals in a short time. BERTs can

also be used to ensure that errors are within the required range. Finally, when all of the signals have been checked, the entire system can be tested with Agilent's protocol analyzers and exercisers. You can stress your design with very specific and controllable worst-case scenarios to give you the confidence that your system is ready to ship.

Agilent has the knowledge, tools, and methods to help you move to the next level in system performance by addressing all of the signal integrity issues. You may have to look at the signal integrity problem from a different perspective, but with Agilent's help, you will not be looking at it alone.

**Figure 1.** Agilent Technologies helps you address signal integrity and jitter issues throughout the entire design process.

# Oscilloscopes and Probes

Prototype Characterization

Bring-Up Test

When you suspect a signal integrity-related problem, the first instrument you grab is an oscilloscope. The scope is the best instrument for finding out what a signal looks like. It will continue to be an important tool for understanding signal integrity problems, but it is only one of many tools that are now required.

You will need a scope that can accurately measure sub 50 ps edge rates. The Infiniium 80000 Series provides up to 13 GHz bandwidth and an intuitive Windows® interface that makes it easy to analyze signals and get the information you need. It can characterize critical signal parameters, such as setup and hold time violations, edge rates, overshoot, and jitter.

As an experienced scope user, you know that your measurements are only as good as your probing system. And as bandwidth increases, it's increasingly important to ask the question: am I measuring my circuit or my scope probe? Nothing is more frustrating than chasing down an apparent design problem, only to find that it was caused by an inferior scope probe.

Together, the newest Infiniium scopes and the innovative InfiniiMax high-performance probing systems offer an end-to-end measurement system with unmatched performance, accuracy and connectivity. InfiniiMax II probes, with up to 13 GHz bandwidth, can measure differential and single-ended signals. Their flexibility supports even the most demanding mechanical access requirements without sacrificing performance. The result is measurements you can trust and better insight into circuit behavior.

When you are developing even faster systems that have edge rates less than 40 ps, you will need a scope with significant bandwidth. The 86100C Infiniium DCA-J accepts modules that provide up to 80-GHz of electrical bandwidth. A remote sampling head for the 86100C allows the user to minimize bandwidth loss due to long cables.

Testing today's high-speed serial buses is simplified with application software for the Infiniium 80000 Series oscilloscopes. Perform mask testing and characterize serial data streams that employ embedded clocks and 8b/10b encoding. Verify compliance to standards such as PCI Express, Serial ATA, DVI, and Gigabit Ethernet.

Characterizing jitter is easy using the Infiniium 80000 Series real-time oscilloscope or 86100C Infiniium DCA-J with the optional jitter analysis software that include histogram, spectrum, and random/deterministic jitter (RJ/DJ) separation capabilities.

**Figure 2.** The Agilent 80000 Series Oscilloscopes and InfiniiMax II Series probes deliver a high-performance 13 GHz end-to-end measurement system.

**Figure 3.** The Agilent 86100 DCA-J is a digital communications analyzer, a wide-bandwidth oscilloscope, a jitter analyzer, and a time-domain reflectometer.

## Logic Analysis System

Prototype Characterization

Bring-Up Test

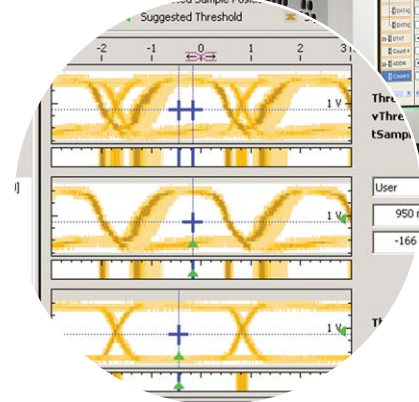

System Integration & Functional Validation

Hundreds of signal traces moving data along wide data paths at high speeds can present quite a challenge to the high-speed digital designer. The interaction of these hundreds of signal lines keeps signal integrity in the forefront. You must validate the signal integrity of each signal path in order to be fully confident of your design.

The typical method for validating all of the signals is to use a 2- or 4-channel scope and measure eye diagrams. This can take a considerable amount of time and is often deleted from the project as many back-end tests fall victim to sliding schedules. The ideal alternative to making hundreds of eye-diagram measurements with a scope is a novel technology called “eye scan.”

With eye scan, you can have the same eye-diagram capability in a logic analyzer that you have in your scope, and cover up to 340 channels at a time. Eye scan gives you a rapid, comprehensive overview across hundreds of signals simultaneously. Eye scan is available in the Agilent 1680/1690 Series standalone logic analyzers and the 16950A, 16760A, 16750 Series, and 16740 Series logic analyzer modules for the 16900 Series logic analysis systems. If eye scan finds a bad signal and you need more detail, you can take a closer look by making a time-correlated measurement between the logic analyzer and an Agilent oscilloscope.

The Agilent 16760A provides a 1.5-Gb/s state acquisition rate and 128-M sample memory depth. It can acquire differential signals with a probing system that presents only 0.7-pF capacitive

**Figure 4.** View the eye diagrams of many channels simultaneously with a logic analyzer and spot sub-nanosecond problems faster than conventional methods.

loading to preserve your system's signal integrity. It has an equivalent bandwidth of 2.33 GHz when using eye scan.

On your next project, use Agilent's innovative, time-saving eye scan technology for a comprehensive overview of the system's signal integrity. Immediately spot problems and identify the offending signals. Use the time you gain to check out signal integrity under all conditions.

Quality measurements start at the probe tips. Agilent's soft touch probes meet the demand for accuracy and reliability while providing connectorless contact with your device. Available in single-ended and differential versions, the contact approach also minimizes multi-layer board

layout issues. With less than 0.7 pF capacitive loading, you can maintain tight timing margins with the soft touch probe attached to your board.

**Figure 5.** Agilent's soft touch probes combine high-density, low loading and differential capability into a reliable space-saving package.

High-speed system design starts with the physical structure. The extreme data rates on the latest high-speed, differential buses are equivalent to sending microwave signals through copper structures. First-pass success demands a systematic approach to design and validation. Microwave engineers have addressed similar design challenges by breaking down the system to model each component separately, then together as a complete channel. This successful approach is now applied to high-speed digital design.

Accurate simulations require accurate component models. You can modify existing models or rely on supplied libraries but the most accurate method is to measure actual components.

Measurement-based models increase your confidence by providing real-world data to your time domain or frequency domain simulator.

Process variations, connector wear and silicon aging erode signal integrity margins. The more accurately you know the transmission and reflection properties of your channel, the less design margin is required.

Two choices are available to design and extract measurement-based models with either a Time Domain Reflectometer (TDR) or a 4-port Vector Network Analyzer (VNA). Each have unique advantages and both produce similar results. TDRs are more affordable and familiar while VNAs produce more accurate and traceable results.

### TDR/TDT

A TDR combines a sampling oscilloscope with a step generator capable of launching a fast edge into the Device Under Test (DUT). The time, location and magnitude of the reflected wave (TDR) provide an easy to interpret display of impedance discontinuities vs. distance. The transmitted wave (TDT) enables you to measure propagation delay and signal deterioration due to system loss and reflections. Measurement errors due to cables, fixtures and probes can be removed through a calibration technique unique to the Agilent 86100C DCA-J/TDR, called Normalization.

The Agilent 86100C Infiniium DCA-J and 54754A Differential TDR module provide an intuitive tool for debug, analysis and model extraction. Excess inductance and capacitance measurements determine the location and magnitude of discontinuities. When not in TDR mode, the 86100C DCA-J operates as a wide-bandwidth oscilloscope with over 80 GHz coverage, depending upon the module used.

For resolution of even smaller discontinuities, Agilent's 86100C DCA-J works seamlessly with Picosecond Pulse Lab's Source Enhancement Module. Measurements can be performed for single-ended and differential measurements with edge speeds under 10 ps and resolutions at a fraction of a millimeter. This solution also works well with Agilent-developed normalization techniques.

#### 4-Port Vector Network Analyzer (VNA)

A VNA uses stimulus/response to characterize the DUT. A sine wave is transmitted into the DUT while tuned receivers are swept in lockstep, providing both reflection and transmission properties. VNAs offer greater measurement resolution and accuracy than a TDR through calibration and fixture removal techniques that have been refined through years of demanding microwave applications. VNA results are calibrated using frequency domain artifacts — each measurement is accurate, repeatable and traceable to industry standards.

VNA measurements are often expressed as Scattering Parameters (or S-Parameters) that can be translated into time-domain views. S-Parameters are well established as the best technique to characterize the manner in which a component modifies a digital signal.

**Figure 6.** Gather accurate measurements for model extractions and comprehensive physical-layer characterizations with the Agilent 86100C DCA-J/TDR, PNA Series VNA, and PLTS system.

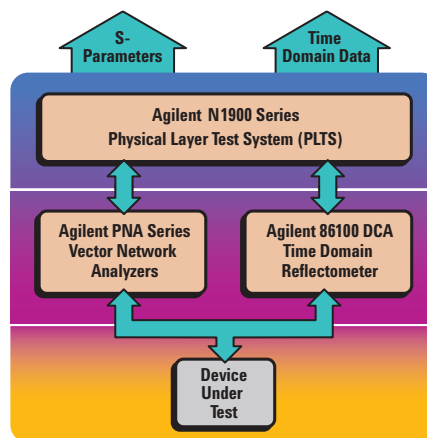

#### Physical Layer Test System (PLTS)

The Agilent PLTS provides confidence in your design through complete characterization and model extraction of your DUT. PLTS supports both the TDR and VNA measurement platforms, providing instrument control including setup, error correction, acquisition and data transfer — thus reducing the difficult and time-consuming process of measuring differential structures to a few keystrokes and reducing the chance of error.

Many high data rate standards require characterizing input differential insertion loss, return loss, impedance and near/far end crosstalk. PLTS provides direct measurement of these

parameters, as well as mode conversion analysis, which is used to understand EMI. Both Serial ATA and PCI Express have adopted the  $S_{DD21}$  parameter (input differential insertion loss) as a required measurement to ensure channel compliance. This parameter indicates the quality of the high-speed serial channel (see Figure 8).

Guided setup and calibration methodologies ensure that the data you capture accurately reflects your DUT. Export VNA or TDR data to simulators that accept S-parameters, such as Agilent's Advanced Design System (ADS).

**Figure 7.** The Agilent PLTS system enables you to control, measure and compare data from both TDR and VNAs.

**Figure 8.** The proposed  $S_{DD21}$  compliance mask for the Channel Electrical Interface (CEI) working group for the Optical Interconnecting Forum (OIF).

# Pulse Pattern Generator

Prototype Characterization

Bring-Up Test

**Figure 9.** The Agilent 81133/4 pulse pattern generator enables the precise characterization of devices and minimizes the influence of jitter injection by the source with superior signal performance up to 3.35 GHz.

While bringing a system up, it is often necessary to stimulate a portion of the system before the entire system is running. A pulse/pattern generator can provide the stimulus signals used by a scope to make eye diagrams. The generator must also allow you to stress the system by adding controllable jitter to the stimulus signal.

The 81134A pulse pattern generator is a high-performance and easy-to-use pulse and data-pattern source for characterizing the physical layer as well as verifying and

validating high-speed clock systems. The graphical user interface enables you to easily set up very complex signals. From generating PRBS to adding jitter to your clock or data, the 81134A gives you the required signals.

With the capability of easily uploading any data pattern up to 12 Mbit, a real life data pattern is easily created.

The fast rise times, low jitter, and full parameter flexibility provide just the signal you need, especially in high-speed systems where timing is critical. Performance can be evaluated with eye-diagram measurements with PRBS from  $2^5-1$  to  $2^{31}-1$ . The delay control

input allows you to add jitter to the clock or data signals. The eye can be distorted with the variable crossover function.

Other features include LVDS levels and a remote graphical user interface and SCPI commands for remote handling and programming.

## ADS, Serial/Parallel BERT, Protocol Analyzers

Link to Model Database

Devices and Interconnect Characterization

Prototype Characterization

Bring-Up Test

System Integration & Functional Validation

Other tools that supplement Agilent's broad coverage of signal integrity include ADS software for simulation, BERTs for determining bit error ratios, and protocol analyzers and exercisers for full system stress and test.

The Advanced Design System (ADS) software from Agilent EEsof EDA provides the design environment, models, and simulation technologies you need to design sub-nanosecond circuits and interconnects. ADS has a wide range of simulation tools and libraries, including a multilayer interconnect library that enables you to accurately model and analyze high-speed interconnect problems before your design is fabricated. This can be accomplished with the built-in libraries, an electromagnetic planar simulator, or measured data supplied by the PLTS, VNA or a TDR.

This tool also allows you to simulate differential S-parameters, eye patterns, noise, jitter, group delay, skew, ground bounce, via inductance, and coupling effects all on a common platform for greater productivity.

Bit error ratio testers (BERTs) enable you to accurately characterize the data quality of your system under various timing and level conditions. By generating a known pattern of data, sending it through your system, and then comparing it to the data leaving

**Figure 10.** BER Scan includes RJ/DJ separation.

the system, you can verify that your system has an error ratio that is low enough to meet your design goals. Serial BERTs are ideal for characterizing single-lane transceiver ports, while multi-port protocols or serializer or deserializer can be verified with Parallel BERTs. All Agilent high-performance BERTs offer a comprehensive measurement suite

for detailed insight for design verification that includes Spectral Jitter Decomposition, BERT scan including RJ/DJ separation, Fast Eye Mask, Output Level, Q-factor and Eye Contour measurements. For

jitter tolerance testing the BERT pattern generators can inject jitter into the device under test.

Once you know that the system transfers data properly, you can use protocol analyzers and exercisers to verify the entire system. These instruments enable you not only to debug and validate your system, but also to stress the system with worst-case traffic in a controlled and repeatable fashion in a realistic system-level environment.

**Figure 11.** Quality simulations from ADS EDA software accurately track real-world measurements.

## Device Characterization and Modeling Services (available in North America only)

[Link to Model Database](#)

Devices and Interconnect Characterization

Not only does Agilent provide you with the tools and training necessary to make the measurements you need, Agilent also provides a signal integrity measurement service that gives you the signal integrity data you need. This service can provide impedance characterization of high-speed interconnects and accurate models for your simulations. Crosstalk, reflected and transmitted losses can be measured. Lossy transmission line models can be derived from measurements that enable designers to accurately predict not only interconnect-induced ringing and reflections, but also amplitude loss, jitter, eye-diagram degradation, and crosstalk.

A qualified Agilent engineer, using the appropriate equipment, can make the following measurements at your site or in an Agilent lab:

- High-speed interconnect impedance measurements
- SPICE model generation and validation from actual measurements of printed and flexible circuit boards, cables, cable assemblies, and connectors
- Frequency-dependent loss modeling, insertion, and return-loss analysis

This is a complete service that alleviates the need for you to purchase the necessary equipment and software and to acquire the expertise to make such measurements. This requires you to provide only the components, prototypes, or test fixtures to be used in the measurement.

For more information about Agilent's professional engineering services (available in North America only), log onto [www.agilent.com/find/si-services](http://www.agilent.com/find/si-services).

## Signal Integrity Channel Partners

### Partner for Success

Agilent Channel Partners are industry experts with world-renowned expertise in Signal Integrity. Their experience combined with Agilent measurement tools can enable you to address both your technical and business constraints, providing what is needed to keep your high-speed digital products on the competitive “leading edge”.

See table on the right for more detail about Agilent's Channel Partners.

### **Agilent Technologies' Test and Measurement Support, Services, and Assistance**

Agilent Technologies aims to maximize the value you receive, while minimizing your risk and problems. We strive to ensure that you get the test and measurement capabilities you paid for and obtain the support you need. Our extensive support resources and services can help you choose the right Agilent products for your applications and apply them successfully. Every instrument and system we sell has a global warranty. Two concepts underlie Agilent's overall support policy: "Our Promise" and "Your Advantage."

#### **Our Promise**

Our Promise means your Agilent test and measurement equipment will meet its advertised performance and functionality. When you are choosing new equipment, we will help you with product information, including realistic performance specifications and practical recommendations from experienced test engineers. When you receive your new Agilent equipment, we can help verify that it works properly and help with initial product operation.

#### **Your Advantage**

Your Advantage means that Agilent offers a wide range of additional expert test and measurement services, which you can purchase according to your unique technical and business needs. Solve problems efficiently and gain a competitive edge by contracting with us for calibration, extra-cost upgrades, out-of-warranty repairs, and on-site education and training, as well as design, system integration, project management, and other professional engineering services. Experienced Agilent engineers and technicians worldwide can help you maximize your productivity, optimize the return on investment of your Agilent instruments and systems, and obtain dependable measurement accuracy for the life of those products.

For more information on Agilent Technologies' products, applications or services, please contact your local Agilent office. The complete list is available at:
